

Elementary TCP Sockets

- *socket* function
- *connect* function
- *bind* function
- *listen* function
- *accept* function
- *fork* and *exec* functions
- Concurrent servers
- *close* function
- *getsockname* and *getpeername* functions

socket Function

```
#include <sys/socket.h>
```

```
int socket (int family, int type, int protocol);
```

returns: nonnegative descriptor if OK, -1 on error

Family	Description
AF_INET	IPv4
AF_INET6	IPv6
AF_LOCAL	Unix domain protocols ~ IPC
AF_ROUTE	Routing sockets ~ appls and kernel
AF_KEY	Key socket

Type	Description
SOCK_STREAM	stream socket
SOCK_DGRAM	datagram socket
SOCK_RAW	raw socket
SOCK_PACKET	datalink (Linux)

Note that not all combinations of family and type are valid.

connect Function: Three-Way Handshake

include <sys/socket.h>

int connect (int *sockfd*, const struct sockaddr **servaddr*, socklen_t *addrlen*);

returns: 0 of OK, -1 on error

(If connect fails, the SYN_SENT socket is no longer useable.)

and before connect : The kernel chooses the source IP, if necessary, and an ephemeral port (for the client).

and error: RST received in response to client TCP's SYN (server not running)
returns ECONNREFUSED

error: 1. no response to client TCP's SYN, retx SYN,
timeout after 75 sec (in 4.4BSD), returns ETIMEOUT
ICMP dest unreachable received in response to client TCP's SYN
(maybe due to transient routing problem), retx SYN,
timeout after 75 sec, returns EHOSTUNREACH

bind Function

assigning a local protocol address to a socket

```
#include <sys/socket.h>
int bind (int sockfd, const struct sockaddr *myaddr, socklen_t addrlen);
        returns: 0 if OK, -1 on error
```

Usually servers bind themselves to their well-known ports. However, RPC servers let kernel choose ephemeral ports which are then registered with the *RPC port mapper*.

Process specifies		Result
IP address	port	
wildcard	0	kernel chooses IP addr and port
wildcard	nonzero	kernel chooses IP addr, process specifies port
local IP addr	0	kernel chooses port, process specifies IP addr
local IP addr	nonzero	process specifies IP addr and port

bind Function (cont.)

... a host to provide Web servers to **multiple organizations**:

Method A: **Aliased IP addresses**

Alias multiple IP addresses to a single interface (*ifconfig*).
Each server process binds to the IP addr for its organization.
(demultiplexing to a given server process is done by kernel.)

Method B: **Wildcard IP address**

A single server binds to the wildcard IP addr.
The server calls *getsockname* to obtain dest IP from the client.
The server handles the client request based on the dest IP.

listen Function

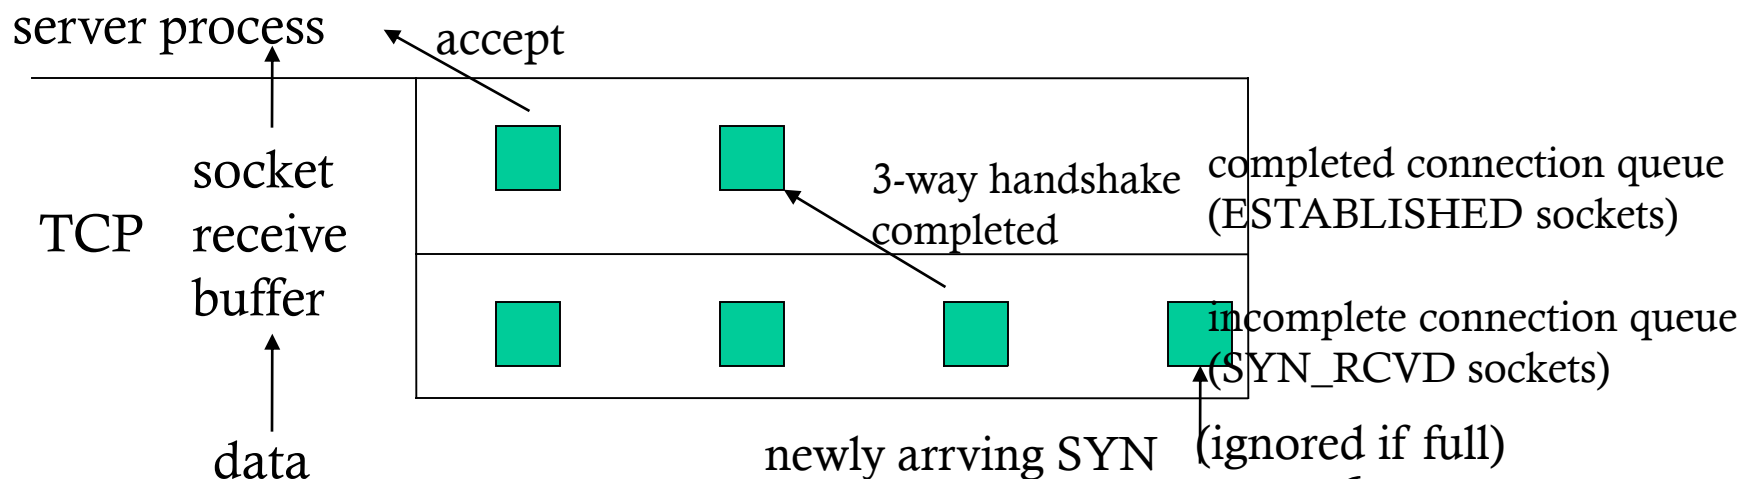

converting an unconnected socket into a passive socket

```
#include <sys/socket.h>
```

```
int listen (int sockfd, int backlog);
```

returns: 0 if OK, -1 on error

For a given listening socket, the kernel maintains two queues and *backlog*, which may be overridden by the environment variable LISTENQ, specifies the maximum value for the *sum* of both queues. However, different implementations interpret differently.

listen Function (cont.)

SYN Flooding : a type of attack due to “backlog”

1. Send SYNs at a high rate to the victim to fill up the incomplete connection queue for one or more TCP ports.
2. The source IP address of each SYN is set to a random number (IP spoofing)
3. Legitimate SYNs are not queued, i.e. ignored.

Thus, the “backlog” should specify the max number of completed connections for a listening socket.

accept Function

returning the new descriptor of next completed connection

```
#include <sys/socket.h>
int accept (int sockfd, struct sockaddr *cliaddr, socklen_t *addrlen);
           returns: nonnegative descriptor if OK, -1 on error
sockfd: listening socket
accept returns: connected socket
cliaddr, addrlen: value-result arguments
```

To examine and display client IP address and port:

```
len = sizeof (cliaddr);
connfd = Accept (listenfd, (SA *) &cliaddr, &len);
printf ("connection from %s, port %d\n",
Inet_ntop(AF_INET, &cliaddr.sin_addr, buff, sizeof (buff)),
ntohs(cliaddr.sin_port));
```

fork and *exec* Functions

```
#include <unistd.h>
```

```
pid_t fork (void);
```

returns: 0 in child, process ID of child in parent, -1 on error
(*called-once-return-twice*)

inheritance: All descriptors open in the parent before fork, e.g. the *connected socket*, are shared with the child.

Two typical uses of fork:

1. to make another copy (e.g. network servers)
2. to execute another program (e.g. shells)

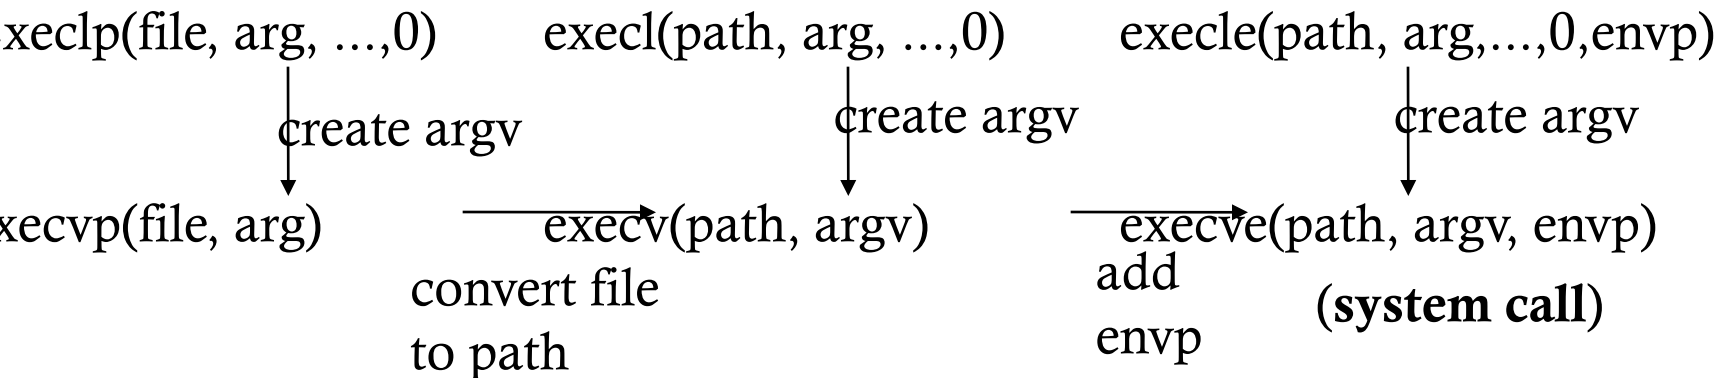

fork and exec Functions (cont.)

```

t execl (const char *pathname, const char *arg0, .... /* (char *) 0 */);
t execv (const char *pathname, char *const argv[ ]);
t execl (const char *pathname, const char *arg0, ... /* (char *)0,
char *const envp[ ] */);
t execve (const char *pathname, char *const argv[ ], char *const envp[ ]);
t execlp (const char *filename, const char *arg0, ... /* (char *) 0 */);
t execvp (const char *filename, char *const argv[ ]);

```

All return: -1 on error, no return on success

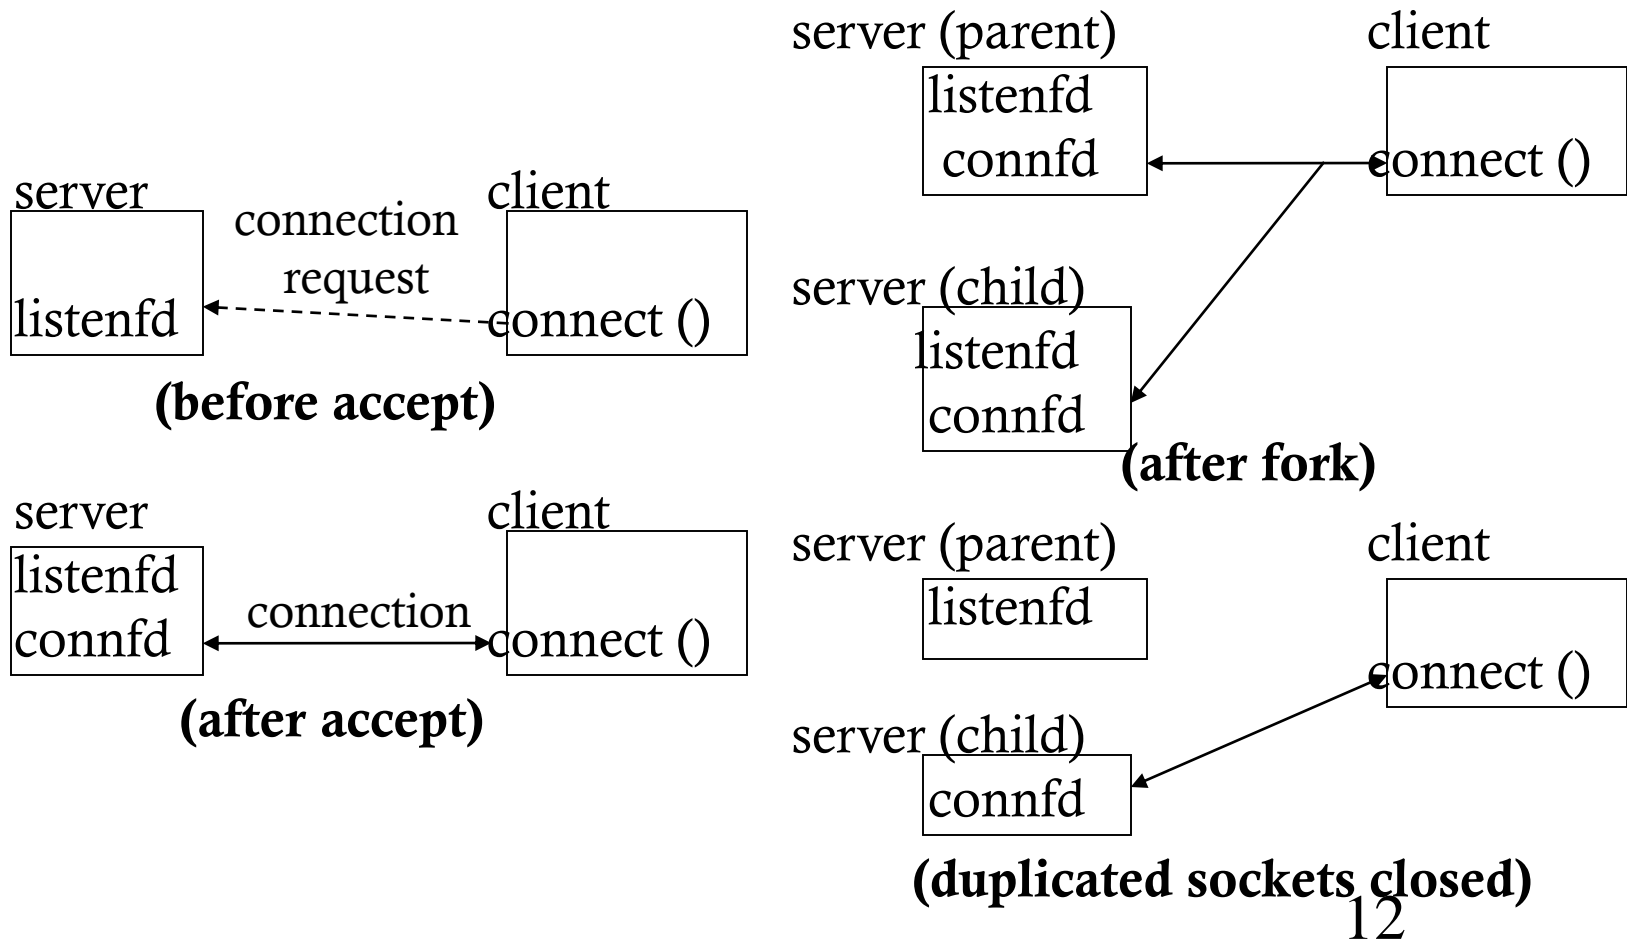

Concurrent Servers: Outline

```
pid;  
listenfd, connfd;  
  
fd = Socket (...);  
in socket_in{} with server's well-known port */  
(listenfd, ...);  
n (listenfd, LISTENQ);  
  
; ){  
fd = Accept (listenfd, ...); /* probably blocks */  
id = Fork ( ) ) == 0) {  
    Close (listenfd); /* child closes listening socket */  
    doit (connfd);    /* process the request */  
    Close (connfd);  /* done with this client */  
    exit (0);        /* child terminates */  
  
e (connfd);          /* parent closes connected socket */
```

Concurrent Servers: Shared Descriptors

Why doesn't the *close* of *connfd* by the parent terminate its connection to the client? ---- Every file or socket has a **reference count** in the *file table*.

close Function

```
#include <unistd.h>
int close (int sockfd);
returns: 0 if OK, -1 on error;
```

Default action of close: (may be changed by SO_LINGER socket option)

- . mark closed and return immediately
- . TCP tries to send queued data
- . normal 4-packet termination sequence

What if the parent does not close connected socket?

1. Run out of descriptors
2. None of the client connections will be terminated.
(reference count remains at 1, termination sequence cannot occur)

getsockname and *getpeername* Functions

```
#include <sys/socket.h>
```

```
getsockname (int sockfd, struct sockaddr *localaddr, socklen_t *addrlen);
```

```
getpeername (int sockfd, struct sockaddr *peeraddr, socklen_t *addrlen);
```

returns: 0 if OK, -1 on error

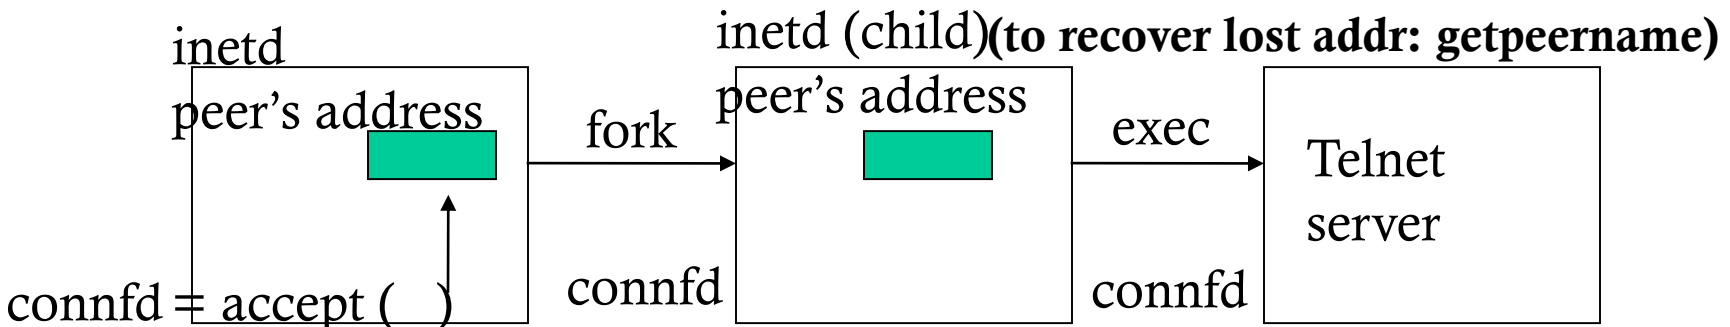

Where are these two functions needed?

• TCP client that does not call bind but needs to know local IP and assigned port

• To obtain address family of a socket

• TCP server that binds the wildcard IP, but needs to know assigned local IP

• A *execed* server that needs to obtain the identity of the client

To know *connfd* after exec: 1. Always setting descriptors 0, 1, 2 to be the connected socket before exec. 2. Pass it as a command-line arg.
